

Assessment Test: Software Tester

Full Name	Jaya Sharma
Email ID	jaya1357sharma@gmail.com
Contact Details	9306551570

Assumptions

Before writing the test cases, I'm noting a few assumptions since there's no existing documentation:

- The app has separate Registration and Login screens.
- Once logged in, a user only sees their own tasks.
- A task has at least a title, and maybe a description and status.
- Validation can happen on both the frontend and backend, so I've covered both angles where it matters.

1. Test Case Design

1.1 Registration

Scenarios covered: registering with valid details, duplicate email, invalid email format, weak password, empty fields, and a couple of edge cases around spacing and long input.

S.No	Scenario	Steps	Expected Result	Type
S1	Register with all valid details	Open the registration page. Fill name, a valid email, and a strong password. Click Register.	Account gets created and user is either logged in or sent to the login page with a success message.	Positive
S2	Register with an email that's already used	Enter an email that is already registered. Fill the rest of the form and submit.	System should block this and show a message like "email already registered".	Negative
S3	Register with an invalid email format	Enter something like "abc@" or "abc.com" in the email field. Submit the form.	Form should not submit, error should say the email format is wrong.	Negative
S4	Register with a weak password	Enter a short/simple password, e.g. "123" or "abc". Submit.	System should reject it and show the password rules (min length, etc.).	Negative
S5	Register leaving mandatory fields empty	Leave name/email/password blank and click Register.	Form should not submit. Each empty required field should show an error.	Negative
S6	Register with extra spaces around email	Enter an email with a leading/trailing space, like " test@test.com ". Submit.	System should trim spaces and register normally, not throw an error because of the space.	Edge
S7	Register with a very long name or email	Enter a name or email that's 200+ characters long.	Either the field should stop accepting more characters, or the system should show a	Edge

S.No	Scenario	Steps	Expected Result	Type
			proper validation error - it should not crash.	
S8	Register with special characters/SQL-like text in fields	Enter something like " OR 1=1 -- " in the name field.	Should be treated as plain text, saved safely or rejected with a validation message, not run as a query.	Edge / Security

1.2 Login

Scenarios covered: correct login, wrong password, unknown email, empty fields, case sensitivity of email, and repeated failed attempts.

S.No	Scenario	Steps	Expected Result	Type
S1	Login with correct email and password	Enter the registered email and correct password. Click Login.	User is logged in and taken to the task list / dashboard.	Positive
S2	Login with wrong password	Enter a valid email but the wrong password. Click Login.	Login fails with a generic message like "invalid email or password".	Negative
S3	Login with an email that doesn't exist	Enter an email that was never registered. Enter any password. Click Login.	Login fails with a generic error - should not reveal whether the email exists or not.	Negative
S4	Login with empty fields	Leave email and/or password blank. Click Login.	Form should not submit, and should show "this field is required" type errors.	Negative
S5	Login with correct details but different letter case in email	Register with "User@test.com", then log in using "user@test.com".	Login should still work, since email is usually treated as case-insensitive.	Edge
S6	Repeated failed login attempts	Enter the wrong password 5-10 times in a row for the same account.	Account should get temporarily locked, or a captcha should appear, to stop brute-force attempts.	Edge / Security
S7	Session stays valid after login	Log in, then refresh the page or open a new tab of the same app.	User should stay logged in and not get randomly logged out.	Positive

1.3 Task CRUD Operations

Scenarios covered: creating, viewing, editing, and deleting tasks, plus checking that deleted data really is gone and that one user can't touch another user's tasks.

S.No	Scenario	Steps	Expected Result	Type
S1	Create a task with valid details	Log in, click "Add task", fill title (and description if any), click Save.	Task is added and shows up in the task list right away.	Positive
S2	Create a task with an empty title	Click "Add task", leave the title blank, click Save.	System should block saving and show a "title is required" error.	Negative
S3	View the task list	Log in as a user who already has a few tasks.	All tasks that belong to that user should be listed correctly - nobody else's tasks should show up.	Positive

S.No	Scenario	Steps	Expected Result	Type
S4	Edit an existing task	Open a task, change the title/description, click Save.	Changes should be saved and reflected in the list immediately.	Positive
S5	Edit a task and clear the title	Open a task, delete all text from the title field, click Save.	System should not allow saving with an empty title, same as creation.	Negative
S6	Delete a task	Click delete on a task, confirm if a prompt appears.	Task should be removed from the list and from the database.	Positive
S7	Delete a task, then refresh the page	Delete a task, then reload the whole page.	Deleted task should not come back after refresh - confirms it was actually removed from the database, not just hidden.	Edge
S8	Create a task with a very long title/description	Enter a title or description with 1000+ characters, click Save.	System should either limit the characters or handle the long text without breaking the layout or crashing.	Edge
S9	Try to edit/delete another user's task directly	Note down another user's task ID (from URL or API), try to open/edit/delete it while logged in as a different user.	Should be blocked with an access-denied type error - one user should never touch another user's tasks.	Security

1.4 Input Validation & Error Handling

Scenarios covered: whitespace-only input, script injection, clarity of error messages, and behaviour during network issues.

S.No	Scenario	Steps	Expected Result	Type
S1	Submit forms with only spaces as input	Type only spaces in a required field like task title or name, then submit.	Should be treated as empty and rejected, not accepted as valid text.	Negative
S2	Enter HTML/script tags in any text field	Type something like <code><script>alert(1)</script></code> in the task title or description.	Should be shown as plain text on screen, not actually run as a script.	Security
S3	Check error messages are clear and field-specific	Trigger validation errors on different fields one at a time.	Each error message should clearly point to the field and the actual problem, not a generic "something went wrong".	Positive
S4	Network/server error while saving	Simulate a slow or failed network call while saving a task (or turn off wifi briefly).	App should show a proper error message and not lose the data the user already typed, or freeze.	Edge

2. Bug Identification (Static Review - No Execution)

These are potential bugs and risk areas I'd expect to check for, just by looking at the feature list, without running the app yet.

S.No	Bug / Risk Area	Severity	Reason / Impact
1	No password strength rule enforced during registration, so users can set very weak passwords like "1234".	Major	Makes accounts easy to guess or brute-force, which is a security risk before going live.
2	Tasks belonging to one user might be visible or editable by another user (missing ownership check).	Critical	This is a data privacy/security issue - one user could see or change someone else's tasks.
3	Deleting a task might only remove it from the screen but not from the database.	Major	Data would still exist and could reappear or cause confusion, and it wastes storage.
4	No limit on failed login attempts, so brute-force password guessing is possible.	Major	An attacker could keep trying passwords until they get in.
5	Task title field may accept an empty value if only spaces are typed in.	Minor	Leads to blank-looking, meaningless tasks cluttering the list.
6	Error messages might be too generic (e.g. "Error occurred") instead of telling the user what actually went wrong.	Minor	Confuses users and makes it harder for them to fix the problem themselves.
7	Long text in task title/description might break the page layout or get cut off oddly.	Minor	Looks unprofessional and can hide important information from the user.
8	Session might not expire properly, so a user stays logged in on a shared or public computer.	Major	Security risk - the next person on that computer could access the previous user's account.
9	Email field might not be checked for a proper format on the server side, only on the frontend.	Major	Anyone bypassing the frontend (using an API tool) could send junk data straight into the database.
10	Refreshing the page right after adding/editing a task might show old data for a moment (caching issue).	Minor	Creates a confusing experience where the user isn't sure if their change was actually saved.

[Account] Version 3.0 Build

© 2016-2026. Powered by VirtuBox. All Rights Reserved.

1. There are two login options on the page - Mobile Number and Email Address.
2. For email login, you have to enter your email, and the system sends a verification code (OTP) to that email instead of asking for a password.
3. Once the OTP is sent, a "Verification Code" field appears where you enter the code you received, and then you will login in the page.
4. If the OTP is incorrect it show "Invalid OTP!"
4. But in your website(VirtuBox) when we login then it show same pop -up like "OTP has been sent!" but the email id is incorrect.

3. Closing Note

This isn't a complete or final test document - given more time, I'd also add test cases for things like password reset, logout, pagination on the task list, and concurrent edits by the same user in two tabs. But this covers the core flows (registration, login, task CRUD, and validation) with a mix of positive, negative, and edge cases, along with the risk areas I'd flag before this goes to production.
